Paypoint

MVP & Near-Term (6–12 month) Roadmap — commerce infrastructure for Africa's social sellers.

VERSION

2.0 — Final (ready for sign-off)

CONFIDENTIAL

PM confidence statement. Paypoint is pre-launch (Pre-Seed, 2026). Every user-behavior and market figure below is a *grounded assumption* unless explicitly marked verified. The strongest evidence is structural (GSMA: 56% of Nigerian MSMEs sell *only* via social media) and behavioral (the "send your account number + screenshot" status quo is universal). The single most load-bearing untested assumption — *that a stranger will trust and complete a Paypoint checkout* — is also the entire business. The MVP is therefore deliberately scoped as an instrument to falsify that assumption fast and cheaply.

What changed in v2.0 (after adversarial review). Three things were materially under-specified or contradictory in v1.0 and are now resolved as load-bearing decisions: **(1) the settlement architecture** — Paypoint uses **Paystack Subaccounts**, so settlement routes to the seller's bank and the fee is split by Paystack; Paypoint never receives buyer funds (this is the technical fact the entire "never holds funds" posture depends on, and v1.0 left it ambiguous against a single-secret-key build spec); **(2) a minimal events table** is now a Must-have, because half the metrics — including the North Star denominator — were uninstrumentable on the locked 3-table schema; **(3) money-integrity completeness** — failed-payment, refund/reversal, abandoned-row, and deactivate-mid-checkout flows are now specified, because a money product that misrecords payments is not shippable. Buyer-PII retention is corrected from 6–7yr to a 90-day minimum (Paypoint is not the statutory record-keeper). Two locked-mockup defects (the AA-failing avatar and the placeholder image) are flagged non-authoritative and corrected. Public/press copy is brought into line with the substantiated, measured numbers.

0. TL;DR / Press Release

FOR IMMEDIATE RELEASE — Lagos, Nigeria. Today Paypoint launches the fastest way for Africa's social sellers to get paid. Any Instagram, WhatsApp or TikTok seller — fashion vendors, food sellers, beauty merchants, coaches, event organisers, digital creators — can turn a product or service into a clean, trustworthy, shareable payment page in about a minute (as fast as 30 seconds), with no website and no code. The seller shares one link (or a QR code) in their bio, a post, or a DM; the buyer pays on a branded checkout; and the money settles **directly to the seller's own bank account via Paystack — Paypoint never holds the funds**. It replaces the awkward, fraud-prone ritual of "*send me your account number and screenshot the transfer*" with a real checkout. "Selling online in Nigeria shouldn't require a developer or a leap of faith from your buyer," said Yvonne, founder. "Paypoint gives every social seller a real checkout — and keeps their money theirs."

FAQ

- 1. Does Paypoint hold my money?** No. Ever. Payments are processed by Paystack and settle straight to the bank account you connect, via a Paystack Subaccount in your name. Paypoint has no wallet, no balance, and never receives or touches your funds. This is a deliberate promise and a regulatory stance.
- 2. Why would a buyer who's never heard of me trust the page?** Because the checkout carries *your* business name and logo, shows how many people have already paid, says "Payments processed by Paystack" (a name Nigerians already trust with money — card details are entered on Paystack's secure page; Paypoint never sees them), shows how to reach you, and issues an instant receipt with a reference number.

3. **What does it cost?** Creating and sharing a page is free. On the Pro plan (custom domain, unlimited pages, branding, analytics) we charge a subscription. On free pages, our small commission is **collected by Paystack as a split at the moment of payment — we are never paid out of your money before you are.** Compared to ~~N5,000–N6,500~~/month gates on heavier competitors, your first Paypoint costs nothing.

Voice note (binding): no copy — press, FAQ, in-app — may claim or imply buyer protection, refunds, or that the page is "as safe as it is." Paypoint does not adjudicate disputes (§3). Substantiated trust claims only: "processed by Paystack," "instant receipt with a reference number," "money goes straight to {business}'s bank."

1. Problem Statement

The problem: A Nigerian social seller can reach thousands of buyers from their phone, but the moment a stranger says "I want it," the sale falls into a trust hole. The seller types out an account number; the buyer hesitates to send money to a personal account they can't verify; the buyer transfers and sends a screenshot; the seller can't tell a real transfer from a Photoshopped "alert"; reconciliation is a notebook and mental math.

Getting paid is the single weakest, least-trusted, most fraud-exposed step in the transaction — done with tools (a raw bank account number) that signal "amateur" or "scam" to exactly the cautious stranger the seller needs to convert.

Evidence

Type	Evidence	Confidence
Behavioral (verified-structural)	56% of Nigerian MSMEs sell <i>only</i> via social media; ~75% touch social channels (GSMA 2023), against ~39.6M MSMEs (SMEDAN/NBS Dec 2021). A huge population selling on channels with no native checkout.	High
Behavioral (observed)	"Send account number + screenshot the transfer" is the universal incumbent — free and habitual, the true competitor.	High
User (assumed, pre-launch)	Sellers report shipping against fake transfer screenshots; rank "get paid before I ship" top-2; distrust any tool that <i>holds</i> their money. (<i>Assumption — validate via 8–12 seller interviews; Risk #10.</i>)	Medium
User (assumed, pre-launch)	Buyers default to suspicion of new account numbers/links, look for trust signals, abandon in seconds if a page looks off or breaks in the WhatsApp in-app browser. (<i>Assumption — validate via live buyer funnel test; Risk #1.</i>)	Medium
Competitive (verified)	No incumbent owns the ~30-second, no-website, single-link job for a non-technical IG/WhatsApp seller. Selar is creator/digital-skewed and expensive (4% + ₦50); Bumpa/Catlog are subscription suites (₦5k–₦6.5k/mo) over-built for a first checkout; Paystack's own Payment Pages/Storefront are generic and not social-seller-onboarded.	High

The opportunity: own the job everyone touches and no one has nailed — *the fastest path from "DM me" to a trustworthy, paid checkout, for a seller who will never build a website* — and let every branded checkout recruit the next seller.

2. Goals & Success Metrics

North Star Metric: Checkout conversion rate on `/p/:slug` = `count(distinct successful, non-test payments) ÷ count(distinct genuine checkout viewers)` per active page per rolling 7-day window.

Rationale: the whole business is whether a stranger pays. It captures buyer trust (the binding constraint), seller value (they get paid), and indirectly the viral loop. It cannot be gamed without real money moving.

Instrumentation note (critical — closes the metrics critique). The locked schema (`profiles` , `pages` , `payments`) records **no view, funnel, or share events** and `payments` has only `created_at` . The North Star denominator and several CRO/funnel metrics were therefore **uninstrumentable as drafted**. v2.0 makes a minimal **events table a Must-have (M13, §9)** — `events(id, page_id, anon_id, event_type, source, ua_class, created_at)` where `event_type` ∈ {view, pay_tap, pay_initiated, receipt_rendered} , `anon_id` is a first-party localStorage UUID, and `ua_class` flags WhatsApp/IG/Facebook/Twitter crawlers so OG-unfurl prefetches are **excluded** from view counts. Every metric below names its source.

Goal	Metric (precise definition)	Source	Baseline	Target	Window
Buyers trust & complete checkout	North Star. <code>distinct anon_id with success ÷ distinct genuine-view anon_id</code> , segmented <code>image_url IS NOT NULL</code> vs <code>NULL</code> , pages with ≥20 unique views (min-n gate)	<code>events</code> + <code>payments</code>	None (new)	Photo segment ≥40% AND ≥10pp above no-photo segment	rolling, 90 days post-launch
Sellers reach "aha" (get paid)	Time-to-A1 = <code>median(first non-test success.created_at - profiles.created_at)</code> over sellers with ≥1 page	<code>payments</code> + <code>profiles</code>	None	Median < 72h	90 days
Onboarding is ~30 seconds	Time-to-first-page = <code>median(pages.created_at - create_started_event)</code> , first page per seller	<code>events</code> + <code>pages</code>	None	Median < 90s; p25 < 30s	rolling 30 days
Sellers come back	W1→W4 paid-active retention = % of <i>week-1 paid-active sellers</i> who are paid-active again in <i>week 4</i> (paid-active in week N = ≥1 non-test success that ISO week) — a single cohort number	<code>payments</code>	None	≥ 35%	cohorts whose W4 falls in first 120 days
The loop recruits sellers	Viral K = <code>(new sellers in 14-day cycle with referred_by_user_id set who reach A1) ÷ (sellers who shared a ref-tagged surface in prior cycle)</code> , reported with attribution-coverage %	<code>profiles</code> + <code>events</code> (ref_click)	None	K ≥ 0.15 by day 90 (coverage ≥60%) → on path to 0.3 at 6mo	6 months
In-app browser doesn't eat payments	Receipt-reach = % of <code>pay_initiated</code> rows that fire <code>receipt_rendered</code> , segmented by <code>ua_class</code> (WhatsApp/IG in-app)	<code>events</code>	None	≥ 98% , no segment < 95%	Launch + ongoing
Money records are correct	Stuck-pending = <code>pending rows >15min old that Paystack /verify returns success ÷ Paystack-verified-success rows</code> (computed by the reconciliation sweep)	sweep + Paystack	None	< 0.5%	rolling 24h, Launch + ongoing
Social proof is true	Re-running <code>verify</code> on the same <code>paystack_reference</code> does not change <code>customers_served</code> (test-asserted); count derived as <code>count(success AND is_test=false)</code>	CI + <code>payments</code>	n/a	idempotent; 0 test/self payments in count	every release
Data boundary holds	Anon <code>SELECT user_id FROM pages</code> denied; <code>SELECT * FROM payments</code> → 0/denied; RPC response keys ⊆ allowlist	CI	n/a	0 leaks (red CI blocks deploy)	every release

Zero-custody is an invariant, not a metric (moved to §8 controls): monthly audit asserts **0 Paypoint bank-settlement entries originating from buyer transactions**; the fee reaches Paypoint only via Paystack Split (commission to Paypoint's subaccount) or seller-side Pro billing — never by Paypoint receiving and netting buyer funds.

PM note on targets. 40% checkout conversion and <72h A1 are *aspirational hypotheses*, not forecasts. The pre-launch buyer-funnel test (Risk #1) gates them: if it returns <60% land→pay on instrumented links, we re-scope before public launch. **Baseline freeze:** the **30-day post-launch North Star value is named baseline B₀**; all later "+Xpp vs baseline" targets (e.g. \$10 epic 1) are measured against B₀ on the equivalent (photo, ≥20-view) segment.

3. Non-Goals (and why)

We are NOT building (this cycle)	Why
Any funds-holding: wallet, balance, escrow, payout, "cash out"	Deliberate strategic + regulatory choice. Holding funds requires a CBN MMO licence and destroys the "your money, your bank" message. Permanent for the foreseeable horizon.
Buyer dispute resolution / escrow protection	We never hold funds, so we <i>cannot</i> offer escrow. No copy may imply buyer protection or refunds (\$0 voice rule). Buyer reassurance is via receipt + reference + seller contactability, not adjudication.
Refund/chargeback adjudication — but Paypoint must still reconcile reversals	Refunds are initiated by the seller in their Paystack dashboard (their account, their money). Paypoint does not process refunds, but it does listen for Paystack <code>refund.processed</code> / <code>charge.dispute.*</code> webhooks and flips the row to <code>reversed</code> / <code>refunded</code> , decrements <code>customers_served</code> , and excludes it from totals — so social proof and "Total collected" never lie. (<i>Closes completeness #3; not a new feature, a money-integrity must.</i>)
Storefront / multiple products per seller	Roadmap (Next, 6–12mo). MVP proves the single-link loop first; storefront is the heaviest, lowest-confidence build (RICE 125) and must be demand-validated (Risk #8).
Custom domain / custom link, Pro subscription & billing, analytics dashboards	Phase-1 monetization, gated behind Pro, which must exist first.
Multi-currency	NGN-only at MVP. The <code>currency</code> column is forward-compatible but only <code>'NGN'</code> is supported and rendered; diaspora buyers pay foreign cards charged in NGN by Paystack. (<i>Closes completeness #14.</i>)
Second payment route (Flutterwave)	Designed-for from day 1 (same initialize→verify pattern) but built only when triggered by Paystack downtime/fee/term risk.
CBN PSSP direct processing	24-month independence play; a 9–18mo licensing program. Near-term roadmap rides Paystack with no Paypoint licence.
KYC / BVN / NIN / DOB collection	None needed to render a checkout. Collecting it pulls Paypoint toward KYC/AML obligations it has no licence basis for. Out.
Personal finance / budgeting (the 2024 brand guideline)	Reconciled OUT. The 2026 product is a focused social-commerce checkout tool.
Payments search/filter	Post-launch fast-follow.
Edit-page flow	Resolved (was a 3-way contradiction): edit is OUT of the launch sprint — the locked <code>/dashboard/pages/:id/edit</code> route and the "Edit" card action are disabled/hidden at launch ; delete-and-recreate is the launch workaround. Edit is the first Wk1–4 fast-follow (§10 NOW), not a permanent non-goal. (<i>Closes completeness #12.</i>)

4. Personas & User Stories

Persona 1 — Amaka the Instagram Vendor (Primary / Seller)

27, Surulere, Lagos. Sells women's ready-to-wear + thrift to ~11,400 IG followers / ~2,800 WhatsApp contacts; ₦350k–~~₦600k~~/mo gross. Android, mobile-data-first, one phone. GTBank + an OPay/Moniepoint wallet. Fluent in IG/WhatsApp/Canva-lite, **not** a website builder, zero tolerance for setup friction. Closes sales in DMs; gets paid by transfer + screenshot; has shipped against a fake alert; tracks orders in a notebook; **will not trust a startup to hold her cash.**

Persona 2 — Tunde the Cautious First-Time Buyer (Secondary but conversion-critical)

31, Lekki, salaried (also represents diaspora buyers paying NGN). A **stranger** to the seller, reached via an IG post or WhatsApp forward. iPhone/high-Android, pays inside the WhatsApp/IG in-app browser on mobile data. Pays by card/transfer; has been scammed or knows someone who has. Spends ~~₦8k–~~₦60k, impulse-leaning. **Defaults to suspicion**, decides to trust in under ~10 seconds, abandons fast, wants an instant receipt as leverage.

Core user stories with acceptance criteria

S1 — Seller: one trustworthy link instead of an account number

As a seller, I want to send one trustworthy link instead of my account number, so I can get paid before I ship without arguing over screenshots.

- **Given** I'm logged in with my Paystack Subaccount connected, **when** I complete the Create form (title + price minimum) and tap Save, **then** a live `/p:slug` link is generated in under ~30s with Copy/QR/Share actions.
- **Given** I have **not** finished connecting Paystack, **when** I create a page, **then** the page is saved as `setup_incomplete` (a distinct state — **not** `is_active`): it is **not publicly shareable** (the Share/QR/Copy actions are disabled with "Connect Paystack to start getting paid"), and any direct hit on its slug returns the calm "This page isn't available yet" state, **excluded from North Star view counting**. (*Closes completeness #2 — no shareable dead-end Pay button.*)

S2 — Seller: look like a real business

As a seller, I want my checkout to look like a credible business, so I can convert strangers and reduce haggling.

- **Given** I've set a business name + logo, **when** a buyer opens my page, **then** the header shows my logo + business name (fallback: my initials on indigo with a **white** glyph — never ink-on-indigo, never a generic mark with no identity).
- **Given** ≥ 1 **real, non-test, non-self** successful payment, **when** the page renders, **then** "★ N paid" shows the true count derived as `count(success AND is_test=false)`; **given** 0, **then** the social-proof row is hidden entirely. (*is_test and seller-as-own-buyer A0 payments never count — closes consistency #5.*)

S3 — Seller: money lands in my own bank + clean records + I'm told instantly

As a seller, I want money to settle to my own bank and a clean record of who paid, so I can ship confidently.

- **Given** a buyer completes payment, **when** Paystack confirms (webhook or callback, whichever first, idempotent on `paystack_reference`), **then** the row flips to `success`, `customers_served` reflects the true derived count, settlement routes to **my Subaccount's bank**, and I get a **real-time "you got paid" email** (see channel below).
- **Given** a payment is unverified, **when** I view the dashboard, **then** it shows an amber `pending` pill, **excluded** from "Total collected" — never shown as paid.

S3a — Seller: the "you got paid" notification channel (was asserted, never specified)

As a seller, I want to know the instant I'm paid even when I'm not in the app.

- **Given** a payment reaches `success`, **when** the settle path runs, **then** an **email** is sent to the seller (channel: transactional email via Resend or Supabase SMTP — **a Must-have dependency, \$7/\$9 M14**) with business name, item, amount, buyer name, Paypoint + Paystack references. (*In-app-only is not a retention cue; web push/WhatsApp are out of MVP scope. Closes completeness #9.*)

B1 — Buyer: confirm it's legit before paying

As a buyer, I want to instantly see the page is tied to the exact seller I'm chatting with, so I can pay without fear.

- **Given** I open `/p:slug`, **when** the page loads ($\leq 2.0s$ LCP on Slow 4G), **then** I see the seller's business name + logo, the real product photo (or a branded neutral state — never a placeholder icon), the price, "Payments processed by Paystack," and tappable seller contact (WhatsApp/IG).
- **Given** the seller deactivated the page, **when** I open it, **then** I see a calm "This page isn't available right now" — never a broken or scam-reading state.

B2 — Buyer: pay in a couple of taps, get proof that survives a closed tab

As a buyer, I want to pay with a method I trust and get an instant receipt I can find again, so I can prove I paid.

- **Given** I tap "Pay ~~XX~~", **when** I'm redirected to Paystack and complete payment, **then** I return to `/pay/callback` and a receipt renders with business name, item, amount, Paypoint reference, Paystack reference, date, and Download/Share.
- **Given** I close the tab on Paystack's page after paying, **when** the webhook fires, **then** my payment still reaches `success` and the seller is notified. **The receipt is reachable at a stable URL** `/pay/receipt/:reference` (sanitized, no seller PII beyond business name/logo/contact), so a buyer who lost the callback tab can still retrieve proof. (*Closes completeness #8 — receipt must not silently fail to reach the buyer; email is not relied on because email is not a required field.*)

B3 — Buyer: a failed or retried payment behaves predictably (NEW — closes completeness #1)

As a buyer, when a payment fails, I want to retry cleanly without confusion, and the system must record it honestly.

- **Given** Paystack returns `failed`, **when** `verify` /webhook fires, **then** the existing row keyed on `paystack_reference` flips to `failed` — **never a duplicate row**; `customers_served` is untouched.
- **Given** I tap "Try again," **when** I re-initialize, **then** a new `paystack_reference` and a new `pending` row are created (one row per Paystack transaction attempt — chosen for clean reconciliation; the prior failed row is retained as `failed`). The North Star denominator is **distinct** `anon_id`, so retries by one buyer do **not** inflate it.
- **Given** I abandon on Paystack's page **before** paying, **when** no verify/webhook arrives within 15 min, **then** the reconciliation sweep moves the row from `pending` to a distinct `abandoned` status, so the stuck-pending metric measures only the dangerous case (Paystack-success-but-unrecorded). (*Closes completeness #6.*)

B4 — Buyer: I paid on a page the seller turned off mid-flow (NEW — closes completeness #7)

As a buyer, if I already paid, my money and receipt must be honored even if the seller deactivated the page after I started.

- **Given** I passed `initialize` while the page was active, then the seller deactivated it, **when** I complete payment on Paystack, **then** `verify` /webhook **still settles and notifies** (money moved — never hidden); `customers_served` increments. `is_active = false` gates **only new** `initialize` calls, never an in-flight payment.
-

5. Solution Overview

Narrative. Paypoint is two physically separate surfaces that never share chrome, state, or session: a **Seller App** (authenticated, app-shell) and **Public Buyer Surfaces** (chrome-free, unauthenticated, sanitized read-only). A seller signs up, creates a page in one short form with a live preview, connects Paystack once (which provisions a Subaccount in their name), and shares a link. A buyer taps that link in WhatsApp/IG, lands on a single trustworthy checkout card, pays via Paystack, and gets a receipt reachable later by reference. Money settles seller-direct to the seller's Subaccount bank. Every checkout and receipt quietly recruits the next seller.

Key UX flows

- 1. Seller onboarding + Paystack connect** — signup → empty dashboard (single CTA) → create page (saved `setup_incomplete`, previewable to the seller only) → **connect Paystack** → "Connected" badge → page becomes shareable/ `is_active`. *Pages are not shareable and not counted until Paystack is connected (S1).*
- 2. Create-a-page** — Product/Service toggle, title, ₦ price (stored as integer kobo), optional photo/description/delivery, buyer-fields-to-collect (Name locked-on), live preview → success panel with Copy/QR/Share.
- 3. Buyer checkout → pay → verify → receipt** — sanitized public read of one active page → fill fields → `initialize-payment` (re-reads price server-side, never trusts client; re-checks `is_active`) → redirect to Paystack → `/pay/callback` → `verify-payment` (idempotent on reference) → receipt; webhook is the authoritative settle path; stable receipt URL by reference.
- 4. Activate/deactivate page** — optimistic toggle; inactive pages return the unavailable state; server re-checks `is_active` at `initialize` only (an in-flight payment always settles — B4).

Screens (reference the locked mockups, **with two mandatory corrections in §6**): marketing landing, seller dashboard (3 metric cards + recent payments), create builder, pages grid, **buyer checkout (the conversion surface)**, receipt.

Key design decisions & trade-offs

Decision	Trade-off accepted	Confidence
Settlement via Paystack Subaccounts (resolved architecture) — connecting "Paystack" provisions/links a Subaccount in the seller's name under Paypoint's integration; <code>initialize</code> sets <code>subaccount</code> + a <code>bearer</code> /split so the seller's bank receives settlement and Paypoint's commission is split by Paystack to Paypoint's subaccount .	More connect-flow work than "paste your public key"; depends on Paystack Subaccount onboarding. Worth it: it is the <i>only</i> model where "settles to the seller's bank / Paypoint never holds funds" is true . The single- <code>PAYSTACK_SECRET_KEY</code> , paste-your-own-key model in the build spec would settle to <i>Paypoint's</i> account (custody — the existential non-goal) or require custodying N sellers' secret keys (a credential/PCI/NDPA liability). Subsumes old Q3.	High
Verify on Paystack webhook (promoted to launch-blocking)	More edge-function + signature-verification work at MVP. Worth it: callback-only produces phantom- <code>pending</code> when buyers close the tab, undercounts <code>customers_served</code> (the social proof driving the loop), and breaks the "you got paid" notification (core retention cue). I overrule the spec's "skip for v1" and the priority team's "fast-follow" — it is a revenue-integrity and trust bug.	High
Redirect-to-Paystack-hosted-page (not Inline/Popup)	Slightly clunkier than an inline card field. Worth it: keeps Paypoint in the lightest PCI scope (SAQ-A class) — card data never touches Paypoint. Switching to Inline risks SAQ-A-EP.	High
Single-product page at MVP (not storefront)	Multi-SKU vendors make multiple pages. Worth it: ships the core loop fast; storefront validated and built in Next. <i>Risk: if >50% of interviewed sellers need multi-product, pull storefront forward (Risk #8).</i>	Medium
Real product photo strongly nudged; branded neutral state, never a placeholder icon	Adds a builder nudge + a neutral state. Worth it: CRO flags placeholder image as the critical anxiety trigger. (<i>The locked mockup's <code>ti-shirt</code> icon is the exact anti-pattern — flagged non-authoritative, §6.</i>)	High
Name-only required by default; warn on each extra field	Sellers may want more data. Worth it: every extra required field likely costs conversion; default to the floor, let sellers opt in with a warning (validate, Risk #12).	Medium
One <code>payments</code> row per Paystack attempt (not row-reuse on retry)	A retried purchase produces multiple rows for one buyer. Worth it: clean idempotency keyed on <code>paystack_reference</code> ; the North Star dedups on <code>anon_id</code> , so the funnel is not inflated.	High

6. Brand & Experience Requirements

Positioning (2026, reconciled — the 2024 personal-finance framing is retired).

For Nigerian social-commerce sellers who close sales with *"send me your account number and screenshot the transfer,"* Paypoint is the ~30-second payment-page tool that turns any product or service into one clean, trustworthy link a stranger will actually pay on — money settling straight to the seller's own bank. Unlike Selar/Bumpa/Catlog (heavier stores you build and maintain) or a bare bank transfer (no trust, no record), we get you to a branded checkout fast, never hold your funds, and put buyer trust first on the one screen that matters: checkout.

Voice: Plain, confident-not-loud, trust-forward, concrete (₦ + names + real numbers), honest, respectful of the seller's time. **Hard rules:** no emojis anywhere; no exclamation marks in-app; never imply Paypoint holds/stores/moves money; **never imply buyer protection, refunds, or self-certified "safety"** (e.g. strike "looks as safe as it is," keep "engineered to convert" out of buyer/press copy — internal CRO language only); use "payment page / your Paypoint" not "store"; "get paid / settles to your bank" not "wallet/balance/cash out"; "₦35,000" (₦ glyph, comma) not "35k". Public claims must match the measured numbers — say "about a minute / as fast as 30 seconds," not a flat "under 30 seconds" (median target is <90s; §2). *(Closes consistency #6, #8, #10.)*

Tone by surface: Checkout = calm, minimal, zero marketing, never leaks seller-app or growth language. Dashboard = brisk, big numbers, quiet labels, no confetti. Marketing = warm, benefit-led, one indigo gradient hero allowed. Errors = honest, never blame the user, reassure that money is safe.

Design system (LOCKED — no additions). Stripe-clean. One accent: Paypoint Indigo `#5F58F4` (hover `#4A43D6`, tint `#EEEDFE`, soft `#F5F4FF`). Ink `#14132B`, text `#33323F`, muted `#6C6B7B`, subtle `#9A99A8`. Bg `#FFFFFF` /soft `#FAFAFE`, border `#ECEBF3`, input border `#E3E2EE`. Status pills (icon + text, never color alone): success `#12B76A`, warning `#F79009`, danger `#F04438`; trust star `#F5A623`. Inter (400/500/600/700), headings -0.01em, prices 700. Radius 8/12/16/20(checkout)/999. Near-invisible shadows; 1px borders do separation. No gradients in-app, no second bright color, no emojis. Mobile-first @375px. Sidebar (≥768px) → bottom tab bar (<768px) from one shared `navItems` config. **Accessibility WCAG 2.1 AA, non-negotiable on checkout/callback:** ≥44×44px tap targets, real `<label>`s, visible indigo focus rings, status by icon+text, `#9A99A8` subtle text restricted to non-essential hints (fails AA as body).

Locked-mockup corrections (mandatory; the mockup is reference, NOT pixel-authoritative where it conflicts with the locked spec). Closes completeness #4 and consistency #7.

- 1. Header avatar contrast.** The checkout mockup renders the fallback `P.` /initials as `color:#14132B` (ink) on `background:#5F58F4` (indigo) $\approx 2.0:1$ — **fails the AA bar the spec calls non-negotiable on checkout. Correction:** white (`#FFFFFF`) glyph on `#5F58F4` (or ink on the `#EEEDFE` tint). The header avatar is **added to the AA-contrast CI check.**
- 2. Image placeholder.** The mockup uses a `ti-shirt` icon on `#EEEDFE` as the image — the exact placeholder anti-pattern CR-1 forbids as the "critical anxiety trigger." **Correction:** when no photo, render the specified **branded neutral state**, never a generic icon; the builder warns before publish.
- 3. Social proof.** The mockup hard-codes "24 paid"; production must derive the true non-test count (S2/CR-4) and hide the row at 0.
- 4. Trust line wording.** Pair "Payments processed by Paystack" once, on first prominence, with CR-2's precise meaning ("Card details are entered on Paystack's secure page; Paypoint never sees them"). (*consistency #8*)

Checkout CRO requirements (buyer trust is the whole business)

ID	Requirement	Addresses	Priority
CR-1	Real product photo mandatory & prominent; if absent, a branded neutral state (never a broken/placeholder feel); builder warns before publish ("Pages with a photo get paid more").	"Is this the real item?"	P0
CR-2	Post-payment trust line: "After payment you'll get an instant receipt with a reference number. Card details are entered on Paystack's secure page; Paypoint never sees them. Money goes to {business} via Paystack."	"Where does my money go?"	P0
CR-3	Tappable seller contact (WhatsApp/IG) on checkout, from profile.	Ghost-fear	P0
CR-4	System-generated social proof "{N} buyers paid here," <code>count(success AND is_test=false)</code> , hidden if 0; never inflated by test/self payments.	"Did she type that number?"	P0
CR-5	Seller logo (fallback white initials on indigo), replacing the generic mark.	"Is this really her shop?"	P1
CR-6	Honest total / delivery clarity; button amount equals what is charged.	Surprise-fee fear	P1
CR-7	Conditional address field for physical products (Address default ON for Product, OFF for Service).	"How will it reach me?"	P1
CR-9	Microcopy under Pay: "You won't be charged until you confirm on the secure Paystack page."	Pre-tap flinch	P1
CR-8 / CR-10	Honest seller-set urgency only (no fake countdowns); inline Nigerian phone validation.	Urgency / data integrity	P2

Measurable CRO success (all from `events` + `payments`, min-n ≥ 20 views/page, rolling 30 days):

view $\rightarrow$ Pay-tap $\geq 55\%$; `pay_initiated` $\rightarrow$ `verified` $\geq 80\%$ (DB-derivable); overall view $\rightarrow$ success $\geq 40\%$ (photo pages) with a **≥ 10 pp observational gap** over no-photo pages (causal lift to CR-1 only claimed if the builder-nudge holdout/A-B runs — see Risk #12); median time-to-pay (`view` $\rightarrow$ `success`) ≤ 45 s; $\geq 85\%$ of **active** pages have a photo (`is_active AND image_url IS NOT NULL` $\div$ `is_active`).

7. Technical Considerations

Architecture. React + Tailwind (mobile-first @375px). Supabase (auth, Postgres, storage, edge functions). Tables: `profiles`, `pages`, `payments`, `events` (new, M13) — **strict RLS on every table** (`events` write-only via the public surfaces' RPC, no anon read). Public checkout served via a **security-definer view/RPC** `public_page_by_slug(slug)` returning ONLY `title, price, currency, description, image_url, delivery_info, collect_fields, customers_served, business_name, logo_url, seller_contact` filtered `WHERE is_active = true` — never `user_id`, buyer rows, secrets, or subaccount codes. Anon role has no direct SELECT on base tables; RPC is **rate-limited** (per-IP) to deter enumeration. Edge functions: `initialize-payment`, `verify-payment`, `paystack-webhook` (promoted to MVP), `reconciliation-sweep` (promoted to MVP — see below). Buyer surfaces (`/p/:slug`, `/pay/callback`, `/pay/receipt/:reference`) import no app-shell module (security boundary + perf: checkout JS ≤120KB gzipped, LCP ≤2.0s Slow 4G).

Settlement & secret-key model (RESOLVED — the load-bearing fact behind "never holds funds"). Closes consistency #2 and completeness #5.

- The build spec's single `PAYSTACK_SECRET_KEY` + "paste your public key" is **Paypoint's own integration key**, used **only** to call Paystack on the seller's behalf with a **Subaccount** that settles to the seller's bank.
- **Connect flow** provisions/links a **Paystack Subaccount per seller** (seller's settlement bank account + percentage charge), storing the returned `subaccount_code` on `profiles` (not a seller secret key — Paypoint never custodies seller secrets).
- `initialize-payment` passes `subaccount` (+ split config) so **settlement routes to the seller's bank** and **Paypoint's commission is split by Paystack** to Paypoint's own subaccount. Paypoint is **never in the money path**.
- The **webhook signature is verified against Paypoint's own** `PAYSTACK_SECRET_KEY` (the integration that owns the transactions) — unambiguous now that the model is settled.

Schema additions to the build spec (decided):

- `payments.status` enum extended to `'pending' | 'success' | 'failed' | 'abandoned' | 'refunded' | 'reversed'` (B3/B4, §3 refund row — money-integrity).
- `payments.paid_at` (timestamp, null until success) and `payments.updated_at` — needed for time-to-pay and reconciliation; `created_at` alone is insufficient.
- **Unique constraint on** `payments.paystack_reference` — settle-once, idempotent; re-running verify on the same reference is a no-op (test-asserted).
- `payments.is_test` — A0/self-test payments never pollute totals, milestone copy, or social proof.
- `profiles.referral_source`, `profiles.referred_by_user_id`, `profiles.subaccount_code`.
- `events` table (M13) as defined in §2 — the analytics sink the North Star and CRO funnel require.
- `customers_served` is **derived/recomputed** as `count(payments WHERE status='success' AND is_test=false AND page_id=...)` (or guarded by the unique-reference settle-once), so callback+webhook double-fire cannot inflate it.

Slug safety (closes completeness #13). Title-derived slug + random suffix, plus: a **reserved-word denylist** (`login`, `signup`, `admin`, `dashboard`, `p`, `pay`, `api`, ...); an **anti-impersonation clause** in the abuse policy (using a known brand in a title is grounds for takedown); rate-limit on `public_page_by_slug` to deter enumeration of active pages.

Email/placeholder hygiene (closes consistency #4). When email isn't collected, `initialize-payment` sends a **non-deliverable, clearly-synthetic, per-transaction** address (`noreply+{reference}@checkout.paypoint.<domain>`) that cannot collide with a real inbox; Paypoint does **not** rely on Paystack to email the buyer when no email is collected — the in-app/stable-URL receipt is the buyer's proof.

Callback/webhook risk (the highest-risk item in the build). Mitigation (decided, in order): (1) **Paystack webhook** → `paystack-webhook` edge function (`charge.success` , plus `refund.processed` / `charge.dispute.*`), signature-verified, as the authoritative idempotent settle path — **launch-blocking**; (2) callback and webhook share one settle function keyed on `paystack_reference` , whichever first wins; (3) `reconciliation-sweep` re-verifies `pending` rows >15min and auto- `abandoned` s **those with no Paystack success — promoted to launch-blocking** because the §2 stuck-pending metric is computed from its output (resolves the v1.0 contradiction where the metric was "Launch" but the sweep was "fast-follow"); (4) `pending` amber, excluded from totals; (5) buyer fallback "Checking your payment... / Refresh status" instead of a hard error.

Risks (technical)

#	Risk	L×I	Mitigation	Measurable signal
T1	Verify-on-callback misses tab-close payments	High×High	Webhook at launch; idempotent settle; sweep auto-abandons orphans	<0.5% Paystack-success stuck <code>pending</code> (rolling 24h)
T2	Redirect round-trip breaks inside WhatsApp/IG in-app browsers	High×High	Device-lab matrix: top-6 Android + WhatsApp/IG in-app iOS+Android, real Paystack test txns	receipt-reach ≥98%, no UA segment <95%; 0 stuck-pending in 100 runs
T3	RLS / sanitized-read leak exposes <code>user_id</code> , buyer rows, or <code>subaccount_code</code>	Low×Existential	Allowlisted view; CI asserts anon <code>select user_id / select * from payments</code> /subaccount denied	0 private fields in public read (CI, red blocks deploy)
T4	Tampered-price attack (client submits amount)	Low×High	<code>initialize-payment</code> always re-reads price + <code>is_active</code> from page row server-side	Client amount never used (code-asserted)
T5	Paystack is rail and competitor (fee/term/throttle/feature land-grab)	Med×High	2nd route (Flutterwave) designed-for day 1; avoid Paystack-only lock-in	Flutterwave adapter passes the same initialize→verify CI suite in staging when built
T6	Live-key / business-verification / Subaccount provisioning delay blocks launch	Med×High	Start Paystack business verification + Subaccount setup today ; build on test keys	Live keys + test Subaccount split confirmed before go-live
T7	Double-settle inflates <code>customers_served</code> /totals	Low×High	Unique <code>paystack_reference</code> ; settle-once; derived count	Re-verify same reference changes nothing (test-asserted)

Open questions (technical) — with owners

Q	Owner	Deadline
Does the full redirect round-trip survive WhatsApp + IG in-app browsers across the top-6 Nigerian Android browsers?	Eng	Before public launch
Which Supabase region (NDPA-adequate vs. document transfer basis)?	Eng + Legal	Before launch
Subaccount split mechanics: percentage charge vs. flat, and bearer of Paystack's own processing fee	Founder + Eng	Before enabling transaction fees

8. Compliance, Security & Privacy (decision-ready)

PCI-DSS — lightest scope (SAQ-A class), by construction. Card data is entered only on Paystack's PCI Level-1 hosted page; Paypoint transmits amount/email/metadata/reference/subaccount — never PAN/CVV/expiry. **Load-bearing rules:** never render a card field in Paypoint; never log/store card data; keep the redirect model (no Inline/Popup without a PCI re-check); secret key server-side only. CI grep for card-field patterns = 0. **[LAWYER/PCI-CONFIRM]** SAQ-A eligibility with Paystack **in writing before launch (hard gate, §11).**

NDPA 2023 / NDPR. Paypoint is a **data controller** for seller PII and (likely) processor for buyer fulfilment PII — *the controller/processor split for buyer data* **[LAWYER-CONFIRM]** determines who owes buyers notices and is reflected in the published policy. **Strengths in design:** data minimization (`collect_fields` — address never default; no BVN/NIN/DOB), sanitized public read, RLS as access-control of record, synthetic non-deliverable placeholder email. **MVP must-do:** publish a plain-language privacy policy (footer + signup + checkout); execute **DPAs with Supabase and Paystack** before launch; choose Supabase region deliberately; designate Yvonne as responsible person.

- **Buyer-PII retention — corrected (closes consistency #3).** Paypoint is **not** the seller's statutory financial record-keeper (the seller/merchant and Paystack are). Default buyer-PII retention on **successful** rows to the **minimum needed for receipt re-issue and dispute contact — propose 90 days** **[LAWYER-CONFIRM]**, after which the purge job nulls buyer name/phone/email/address. The 90-day purge already covers `pending` / `failed` / `abandoned`. The old "6–7yr as financial records" assertion is struck. The open question is reframed: *confirm Paypoint is NOT the statutory record-keeper* **[LAWYER-CONFIRM]**.

CBN PSSP path. Today Paypoint is a **software layer on a licensed PSP (Paystack)** — money settles seller-direct via Subaccounts, Paypoint holds no funds, no licence required (*secure a lawyer's opinion letter for investor diligence — hard gate, §11*). **PSSP is Phase-2** (a PSSP may process/aggregate but **may not hold funds** — aligned). **Capital figure:** the widely-cited PSSP minimum is **₦100M**, not ₦250M (the ₦250M is the *Switching & Processing* tier). **Do not put a hard capital number in the deck without** **[LAWYER/CBN-CONFIRM]** of the current circular. Timeline ~9–18mo — a fundraising/ops project, not gating the near-term roadmap.

The "are we accidentally regulated?" risk — fee collection (now bound everywhere, not just here). Closes consistency #1. *How* the fee is collected determines licensing exposure. **Binding rule across the whole document:** the per-transaction commission is collected **only** via **Paystack Split / Subaccounts** (Paystack routes Paypoint's commission; the seller is the merchant; Paypoint never receives buyer money and never "deducts our fee from buyer money we received" — that is fund-holding). **Until [LAWYER-CONFIRM], lead with the Pro subscription (billed seller-side, off the payment rails) as the primary revenue line.** FAQ #3 and §1 copy are corrected to never imply Paypoint receives and nets buyer funds.

Zero-custody control (the invariant moved out of §2). Monthly audit: **0 Paypoint bank-settlement entries originating from buyer transactions**; CI/audit asserts no Paypoint-owned Paystack balance receives buyer funds (commission only, via split).

Key compliance risks (decision-ready): A1 fee mechanism puts us in the money path (Med×High → Split/Subaccounts, lawyer-confirm before enabling fees); F1 fraudulent sellers (Med×High → Paystack KYC on settlement Subaccounts as first line, abuse-report link on `/p/:slug`, reserved-slug/anti-impersonation policy, fast takedown); D1/D2 RLS misconfig / over-exposed read (Low×Existential → CI tests + pre-launch pen spot-check); R1 regulator deems MVP a regulated service (Low–Med×High → keep money seller-direct, lawyer opinion letter on file).

9. Scope & Prioritized Backlog

MVP boundary: *a seller creates a payment page in about a minute, connects Paystack, shares it, and a stranger pays with money settling to the seller's bank via a Paystack Subaccount — recorded correctly even on tab-close, failure, retry, or mid-flow deactivation. Everything else defers.*

MoSCoW

Must (cannot launch without):

- M1 Email/Google auth + auto-profile
- M2 Schema + strict RLS + sanitized public read (+ extended status enum, unique `paystack_reference`, `paid_at` / `updated_at`)
- M3 Create builder (toggle/title/kobo-price/photo/fields/slug + reserved-slug denylist)
- M4 Public chrome-free checkout `/p/:slug` (branded neutral state, corrected avatar)
- M5 `initialize-payment` + `verify-payment` (server price re-read, `is_active` re-check, idempotent settle, **Subaccount + split**)
- M6 `/pay/callback` receipt (success/failed) + **stable** `/pay/receipt/:reference`
- M7 Routing + auth guards (public never renders app shell)
- M8 Pages grid (active toggle + Copy + Share; **Edit action disabled at launch**)
- M9 **Connect Paystack via Subaccount provisioning** + "we never hold your money" explainer
- M10 Dashboard + Payments table (3 metric cards, recent, status pills)
- **M11** `paystack-webhook` (signature-verified; `charge.success` + `refund.processed` / `charge.dispute.*`) — *promoted from "skip for v1."*
- **M12 PO CRO requirements CR-1/CR-2/CR-3/CR-4.**
- **M13** `events` table + **view/pay_tap/pay_initiated/receipt_rendered capture** — *without it the North Star and CRO funnel are unmeasurable (closes the metrics critique).*
- **M14 Transactional email** ("you got paid" to seller; receipt-by-reference link) via Resend/Supabase SMTP — *the asserted retention cue made real.*
- **M15** `reconciliation-sweep` (>15min `pending` → re-verify → `success` / `abandoned`) — *promoted; the stuck-pending launch metric is computed from it.*
- **M16 A0 self-test flow** — seller pays their own page once (Paystack test-mode detection sets `is_test=true`); excluded from all counts; satisfies the \$10/\$11 "live ₦100 self-test" checklist item.

Should (pulled into MVP — cheap, high-leverage; see RICE): social-proof counter (S5), WhatsApp/X share fallback (S3), QR on cards (S1). PDF receipt (S2) if time. *(These are growth-loop bets, not falsification requirements — if the launch sprint slips they are the first cuts; the 30-second/Copy-link core is protected. Acknowledges completeness #15.)*

Could (post-launch): payments search/filter, "This month" card refinements.

Won't (out — see §3): storefront, custom domain, Pro tier, Flutterwave route, analytics dashboards, funds-holding, PSSP, personal-finance, multi-currency, refund *adjudication* (reconciliation only), edit-page *during the launch sprint* (Wk1–4 fast-follow).

RICE — contested items (Score = $R \times I \times C \div E$)

Item	Reach/qtr*	Impact	Conf	Effort(pw)	RICE	Verdict
Social-proof "N paid" (S5)	1,500	1	70%	0.2	5,250	Pull into MVP
events table + capture (M13)	1,500	3	80%	0.8	4,500	Must (metrics gate)
Webhook (M11)	1,500	3	80%	1.0	3,600	Launch-blocking
Reconciliation sweep (M15)	1,500	2	75%	0.6	3,750	Launch-blocking
"You got paid" email (M14)	1,500	2	75%	0.7	3,214	Must (retention cue)
PDF receipt (S2)	1,500	1	65%	0.6	1,625	MVP if time, else day-2
Trust-signals bundle	1,500	2	60%	2.0	900	Phase 1, first
WhatsApp/X share (S3)	1,500	1	85%	0.4	3,188	Pull into MVP
QR on cards (S1)	1,500	0.5	80%	0.3	2,000	Pull into MVP
Flutterwave 2nd route	1,500	1.5	45%	4.0	253	Phase 2 (trigger-based)
Edit-page flow	1,500	1	90%	0.8	1,688	Wk1-4 fast-follow
Storefront / multi-product	1,500	3	50%	6.0	375	Phase 2 (lead item)
Custom domain	800	2	55%	3.0	293	Phase 2 (behind Pro)
Pro tier + billing	1,500	3	50%	5.0	450	Phase 2

***RICE Reach reconciled (closes metrics #10).** v1.0 used internally inconsistent reach figures (500–8,000) against a 50k–150k SOM. Reach is now a single consistent unit: **active sellers reached per quarter in the first post-launch year**, anchored to a realistic early base (~1,500 active sellers/qtr — well inside the 50k–150k 36-month SOM ceiling, not contradicting it). Scores re-derived; verdicts unchanged on the load-bearing items.

PM override, stated explicitly: webhook, sweep, events, and email are all promoted into Must regardless of raw RICE, because their true impact is **money-integrity, the core retention cue, and metric-measurability** — a money product that silently misrecords payments or cannot measure its own North Star is not shippable. Confidence: High.

10. Roadmap — Now / Next / Later

North Star: checkout conversion rate. Supporting metrics across horizons: time-to-A1, W1→W4 paid-active retention, viral K (with attribution coverage), receipt-reach, <0.5% stuck-pending.

NOW — MVP Launch

Owner: Yvonne (product/GTM) + 1–2 builders. **Window:** launch sprint + Week-1–4 fast-follow.

- Ship M1–M16 + S1/S3/S5. **Exit criteria (all must pass end-to-end before announce):** signup → create page (median <90s, measured via `events`) → connect Paystack Subaccount → chrome-free `/p:/slug` → live ₦100 Paystack payment → **settlement routes to the seller's bank, not Paypoint** → row flips `success`, `customers_served` correct, receipt renders **and is reachable by reference**, webhook confirms, seller gets the "you got paid" email. Plus all \$11 compliance gates green.
- **Fast-follow (Wk1–4): edit-page flow** ("I priced it wrong" is the first complaint); payments search + "This month" card.
- **Success metric:** ≥40% checkout conversion (photo pages); median time-to-A1 <72h.

NEXT — 6–12 months (validated growth). WIP = 1 epic at a time. ~20.5pw ≈ 5–6mo at ~2.5 net pw/wk.

Order	Epic	Owner	Success metric (measurable)	Dependency
1	Trust-signals bundle (verified badge, post-payment review/rating capture, contact-seller surface, Paystack prominence)	Product + Eng	photo-segment NSM ≥ $B_0 + 5pp$ at 30 days post-ship (B_0 = frozen 30-day post-launch NSM)	<code>customers_served</code> , <code>events</code>
2	QR maturation (downloadable, print-ready branded QR; <code>?src=qr</code>)	Eng	≥15% of trailing-30-day active sellers have a page with ≥1 view where <code>source='qr'</code>	MVP QR
3	Pro tier + billing (Paystack recurring; new <code>subscriptions</code> table; gates items below)	Founder + Eng	≥5% of trailing-30-day active sellers hold an active Pro subscription at 90 days post-launch	—
4	Custom link & domain (first Pro perk; CNAME + slug aliasing)	Eng	≥40% of Pro sellers configure a custom domain within 60 days	Pro
5	Storefront / multi-product (one seller → many pages)	Product + Eng	≥20% of single-active-page sellers create a 2nd active page within 60 days of storefront launch	Validate via Risk #8; Pro
6	Second payment route (Flutterwave) behind same initialize→verify pattern	Eng	Flutterwave adapter passes the Paystack initialize→verify CI suite in staging	Trigger: Paystack downtime/fee/term risk

"Active seller" is defined **once, everywhere**: a seller with ≥1 successful non-test payment in the trailing 30 days. (Closes completeness #10, metrics #10.)

LATER — direction only (not specced here)

The 24-month "money OS" vision and the **CBN PSSP licence** (process directly, reduce Paystack dependency, still never hold funds). A Phase-2 fundraising/licensing program (9–18mo), explicitly *not* gating Now/Next.

11. Go-to-Market Brief

Audience: Primary = Nigerian IG/WhatsApp social sellers (fashion, beauty, food, coaches, event organisers, digital creators). Critical secondary = the cautious first-time buyer who must trust the checkout.

Value prop: *"Get paid like a real business — without building one. Turn any product into a payment link in about a minute, paid straight to your bank. We never hold your money."*

Channels:

- **The viral loop (primary, owned):** every checkout footer ("Powered by Paypoint", quieter than the Paystack line, never above Pay), every receipt ("Want a payment page like this? Create one free →" on the *buyer's* view only), the receipt PDF footer, the QR landing, and the **WhatsApp OG link-unfurl** (product image + "Pay securely · Paypoint"). All carry `?ref={surface}&src={slug}` — **seller/surface identifiers ONLY, never any buyer field** (CI/manual check asserts recruitment URLs contain no `payments` columns; the buyer "create your own" CTA sets no cookie/identifier on the buyer — closes consistency #11). Resolves to the recruiting seller's `user_id` → measurable K. Guardrails: Paystack security cue always outranks the growth cue; one brand mention per surface; no interstitials; OG-unfurl prefetches excluded from view counting via `ua_class`.
- Founder-led seed: concierge-onboard 10 real Lagos vendors (also Risk #3 validation).
- Peer referral among vendor clusters; milestone-triggered "tell another seller" at ₦1M / 100 customers.

Launch checklist (all hard gates — closes consistency #9):

- **Compliance:** lawyer opinion letter on file that the MVP is not a regulated payment service · written **SAQ-A eligibility confirmation from Paystack** · **Q4 controller/processor determination reflected in the published privacy policy** · **Supabase region / NDPA transfer basis decided** · privacy policy published · Supabase + Paystack DPAs executed.
- **Technical:** Paystack business verification live · live keys active · **per-seller Subaccount provisioning + split confirmed (settlement routes to seller's bank, verified on a test split)** · webhook live + signature-verified · reconciliation sweep live · `events` capture live · "you got paid" email sending · RLS CI tests green · in-app-browser device matrix passed · A0 self-test flow live · domain + OG tags configured.
- **Final:** **one real ₦100 live transaction end-to-end, after all compliance gates above are green** (settlement lands in the seller's bank, not Paypoint's).

Success criteria (first 90 days): ≥40% checkout conversion (photo pages, ≥20-view min-n); **≥60% land → pay completion AND <15% trust-stage abandon** (trust-stage = viewed ≥10s without `pay_tap`) in the pre-launch buyer-funnel test (gate, ≥50 real buyers); median time-to-A1 <72h; **≥7/10 concierge sellers have ≥1 success OR an active page with ≥5 views in days 8–14**; <0.5% stuck-pending; **K ≥0.15 by day 90 (attribution coverage ≥60%)**.

Rollback: Public routes are static-cheap; if checkout conversion or stuck-pending breach thresholds, (1) kill-switch disables new-page Pay while keeping existing receipts viewable, (2) revert to last-good edge-function deploy, (3) for a Paystack-side incident, communicate "payments paused" honestly on `/p:slug` (never charge silently), (4) if a data-boundary regression is found, take public read offline ("temporarily unavailable") until the CI RLS test is green again.

12. Open Questions & Risks (consolidated)

#	Question / Risk	Owner	Decision deadline
1	Will strangers trust & complete the checkout? (the entire business) — 50–100 real-buyer funnel test; pass = $\geq 60\%$ land $\rightarrow$ pay, $< 15\%$ trust-stage abandon	Product	Before public launch
2	Redirect round-trip inside WhatsApp/IG in-app browsers — device-lab matrix; pass = receipt-reach $\geq 98\%$, no UA segment $< 95\%$	Eng	Before public launch
3	Subaccount split mechanics (percentage vs flat, fee bearer) keep Paypoint out of the fund flow	Founder + Legal	Before enabling transaction fees
4	Controller vs. processor for buyer PII (who owes buyers notices) — reflected in privacy policy	Legal	Before launch
5	SAQ-A eligibility confirmed with Paystack in writing	Legal + Eng	Before launch (hard gate)
6	Supabase region / cross-border transfer basis	Eng + Legal	Before launch
7	Webhook authoritatively confirms $\geq 99\%$ of payments (overrides callback-only)	Eng	Launch-blocking
8	Do $> 50\%$ of sellers need multi-product? $\rightarrow$ if yes, pull storefront forward	Product	Concierge onboarding (Wk 1–4)
9	Per-transaction fee band acceptable vs. free transfer (Van Westendorp, 20+ sellers)	Product	Before enabling fees
10	Current PSSP capital floor (¥100M vs ¥250M; escrowed vs evidenced) — don't quote in deck until confirmed	Founder + Legal	Before fundraise on this number
11	Lawyer opinion letter: MVP is not a regulated payment service	Legal	Before launch (hard gate) + investor diligence
12	Over-collecting buyer fields suppresses conversion; isolate CR-1's causal photo lift (A/B Name-only vs full; builder-nudge holdout for the ≥ 10 pp causal claim)	Product	First 60 days
13	Confirm Paypoint is NOT the statutory financial record-keeper for buyer data (sets 90-day retention vs longer)	Legal	Before launch (privacy policy)

Open questions where I disagree with a critic (decision kept, rationale recorded)

Critic finding	My decision	Rationale
Completeness #15 / metrics: QR + WhatsApp/X share are not needed to falsify the core hypothesis; cut to protect the 24-hour core.	Keep them in MVP as "Should," explicitly first-to-cut.	They are near-zero effort (0.3–0.4pw) and they <i>are</i> the viral loop, which is the second hypothesis the MVP exists to test (every checkout recruits the next seller). I accept the critic's framing — they are growth bets, not falsification requirements — and have written that into §9. But cutting them pre-emptively would under-test the loop. They are cut only if the sprint slips.
Metrics: make <code>customers_served</code> a <i>derived count</i> rather than an incremented integer.	Allow either, but require the unique-<code>paystack_reference</code> settle-once guard regardless.	A derived count is cleanest, but on the locked Supabase build a guarded increment is equally idempotent and cheaper to render on the dashboard. The non-negotiable is the test-asserted invariant (re-verify changes nothing), which I've made a §2 metric and T7. Implementation choice left to Eng.
Completeness #1: on "Try again," reuse the unconsumed pending row.	Create a new row per Paystack attempt instead.	Row-reuse muddies idempotency keyed on <code>paystack_reference</code> (a reused row would carry multiple references over its life). One row per attempt keeps the unique constraint clean; funnel inflation is prevented by deduping the North Star on <code>anon_id</code> , not by minimizing rows.

Appendix

Source documents

- Build spec: `/Users/newmanaruna/Desktop/Paypoint-FE/Brand/MVP PROMPT/paypoint-mvp-build-v2.md`
- Mockups (`/Users/newmanaruna/Desktop/Paypoint-FE/Brand/SCREEN MOCKUPS/`):
`paypoint_marketing_landing_mockup.html` , `paypoint_seller_dashboard_mockup.html` ,
`paypoint_create_builder_mockup.html` , `paypoint_pages_grid_mockup.html` ,
`paypoint_buyer_checkout_mockup.html` , `paypoint_payment_receipt_mockup.html` — **reference, not pixel-authoritative; the \$6 corrections (avatar contrast, image placeholder, derived social proof, trust-line wording) override the mockups where they conflict with the locked design spec.**

Market notes (verified anchors). 39.6M MSMEs (SMEDAN/NBS Dec 2021); 56% sell *only* via social, ~75% touch social (GSMA 2023); Nigeria e-commerce GMV ~\$9.35B (Mordor 2025). ****Do not cite the 12.43B2026social – commercefigure—a publishing error incompatible with the same publisher's 1430–90M routed GMV over 36 months. RICE reach (~1,500 active sellers/qtr in year 1) is consistent with — and well inside — this SOM.**

Competitive notes. Paystack Payment Pages/Storefront — cheapest verified fees (1.5% + ₦100, capped ₦2,000), both the rail and the biggest threat; respond with focus + UX velocity, not feature parity. Selar — 4% + ₦50, digital/creator-skewed. Bumpa (~₦5k/mo) / Catlog (~₦6.5k/mo) — suites over-built for a first checkout; compete on free-at-entry + a seamless single-page→storefront upgrade. Flutterwave Store — de-prioritised. **Bank transfer ("send account number + screenshot") — the true incumbent: free, habitual; beat it on trust, instant verified receipt, no reconciliation, no fake-alert fraud.**

Reconciliations & critic resolutions made by the PM (with confidence).

1. **Settlement via Paystack Subaccounts** — resolves the single-secret-key vs. seller-direct-settlement contradiction; the entire "never holds funds" posture now rests on a stated mechanism. *High.* (Consistency #2, Completeness #5.)
2. **Fee collected only via Paystack Split/Subaccounts**, Pro subscription as primary revenue until lawyer-confirmed; FAQ/§1 copy corrected. *High.* (Consistency #1.)
3. **events table + capture is a Must** — without it the North Star is theater; all metrics re-specified to a measurable source. *High.* (Metrics critique.)
4. **Money-integrity completeness:** failed/retry (B3), abandoned-row sweep, deactivate-mid-flow (B4), refund/reversal reconciliation, extended status enum, unique-reference settle-once, derived/guarded `customers_served` . *High.* (Completeness #1/#3/#6/#7, metrics idempotency.)
5. **Buyer-PII retention corrected to 90-day minimum;** Paypoint is not the statutory record-keeper. *High.* (Consistency #3.)
6. **Webhook + reconciliation sweep promoted to launch-blocking** (overrides build spec "skip for v1" and the stuck-pending metric/sweep contradiction). *High.* (Completeness, metrics #2.)
7. **Mockup corrected, flagged non-authoritative:** white-on-indigo avatar (AA), branded neutral state (CR-1), derived social proof. *High.* (Completeness #4, Consistency #5/#7.)
8. **Public copy aligned to measured numbers and honest claims:** "about a minute," "processed by Paystack," no "as safe as it is," no "engineered to convert" in buyer/press copy. *High.* (Consistency #6/#8/#10.)

9. **Un-connected pages are `setup_incomplete` , not shareable, not counted** — no dead-end Pay button. *High.* (Completeness #2.)
10. **Edit-page is a Wk1-4 fast-follow** (route/action disabled at launch), not a permanent non-goal — three-way contradiction resolved. *High.* (Completeness #12.)
11. **NGN-only non-goal added; slug denylist + anti-impersonation; synthetic placeholder email.** *High.* (Completeness #13/#14, Consistency #4.)
12. **"Active seller" and all NEXT metrics defined precisely; RICE reach reconciled to SOM; baseline B₀ frozen at 30 days.** *High.* (Metrics #10, cross-cutting #4.)
13. **Single-product MVP held** despite multi-SKU prevalence — gated by Risk #8. *Medium.* **2026 social-commerce positioning** retained over 2024 personal-finance. *High.* **\$12.43B TAM still not cited.** *High.*
